

## ME2 Computing- Coursework assignment

### Learning outcomes:

- Being able to identify a PDE for a physical problem
- Being able to choose an appropriate method to solve numerically the PDE
- Being able to implement and code the numerical method

This CW has to be done in groups of two students, of your choice, presenting both the same single report (with consequent common mark).

### Before you start:

In your H drive create a folder `H:\ME2MCP\CW` and work within it

### Tasks:

1. Choose a physics described by a PDE (of any type: i.e. elliptic, parabolic, hyperbolic), from any of the ME1/ME2 modules you have encountered till now or from any Physics of your choice (even outside Mech. Eng. domain).
2. Set the PDE, for the chosen physics, with no more than three independent variables, i.e. three spatial  $(x,y,z)$  or one time and two spatial  $(t,x,y)$ . It does not need to be in Cartesian coordinates.
3. Set the boundary/initial values for the event you wish to analyse.
4. Choose a method to solve numerically the PDE.
5. Work out the maths to discretise the PDE, according to the method chosen.
6. Implement your numerical analysis by using Python.
7. Test the numerical code by using a discretised two-dimensional grid.
8. Repeat the test with a grid ten times finer and discuss about any possible problems of convergence.

### Outcomes:

1. One single Python file (template is on BB).
2. A two pages summary of the work done (template is on BB). Word counting: max 1300.

**Deadline:** Wed 7<sup>h</sup> of April 2021 at 11.59pm (UK time)
